Project Title: LexFlow: Law Firm Case Management Portal

Team Main: Alice Dao, Suhail Tailor, Ynha Nguyen

I. Abstract

LexFlow is a secure web-based case management portal designed to help law firms manage cases, clients, documents, deadlines, and tasks in one organized location. Many law firms rely on separate files, emails, spreadsheets, and other disconnected tools to manage their work. This can make it difficult to locate important information, track case progress, meet deadlines, coordinate responsibilities, and protect confidential client data. LexFlow will address these challenges by providing attorneys and authorized staff with a centralized platform for managing essential legal operations. Users will be able to securely log in, access information according to their assigned roles, create and update case records, manage client information, upload and organize documents, assign tasks, and monitor important deadlines.

Role-based access control will help ensure that users can only view or modify information appropriate to their responsibilities, reducing the risk of unauthorized access. The portal will also include activity tracking so that actions such as creating, editing, viewing, or deleting case information can be recorded for accountability, transparency, and auditing purposes. The project will follow an organized development process that includes requirements analysis, database design, interface planning, implementation, testing, and documentation. The project document will be updated continuously throughout development to record requirements, design decisions, progress, completed features, testing results, and any changes made by the team. This approach will help the team maintain a clear record of the project and ensure that the final system meets its intended objectives.

Functional and security testing will be performed to identify defects, verify user permissions, and confirm that the main features operate correctly. The expected result is a functional prototype that demonstrates how enterprise technology can improve efficiency, collaboration, security, and accountability within a real-world law firm environment. The system may also provide a foundation for future features such as client access, automated deadline reminders, calendar integration, electronic signatures, reporting tools, and cloud deployment. Overall, LexFlow will demonstrate how a secure, centralized information system can support legal professionals in organizing their work and managing sensitive information more effectively.

II. Project Milestones

- Begin requirements analysis, team planning, database design, and interface planning during the week of October 16, 2026.
- Develop authentication, role-based access, and case and client management features by early November.

- Implement document management, task and deadline tracking, activity logs, and security improvements during November.
- Conduct functional and security testing, correct defects, and document test results during the second half of November.
- Complete the final report, presentation, GitHub repository, and demonstration materials by December 4, 2026, subject to the instructor's official deadline.
- Submit the final report, presentation, demonstration video or file, and source code through the team leader.

III. Project Requirements, Equipment, Risks

The project will require secure authentication, role-based access control, case and client management, document organization, task and deadline tracking, activity logging, functional testing, and security testing. The team will use development computers, internet access, a code editor, GitHub, a web browser, a database system, and a suitable web-development framework.

Potential risks include unclear requirements, scheduling conflicts, software integration issues, incomplete features, data loss, and unauthorized access. These risks will be managed through regular communication, version control, backups, staged development, role-based security, continuous testing, and regular updates to the project document.
